

Climate

Today's agenda

The role of the natural atmosphere in the climate system

Human impact on the atmosphere and the climate

- Radiation balance (of the Earth)
- The greenhouse effect
- Radiative forcing
- Climate change

Literature connected with today's lecture:

Jacob chapter 7, and IPCC SPM (on webpage)

Exercises: 7:1 – 7:6

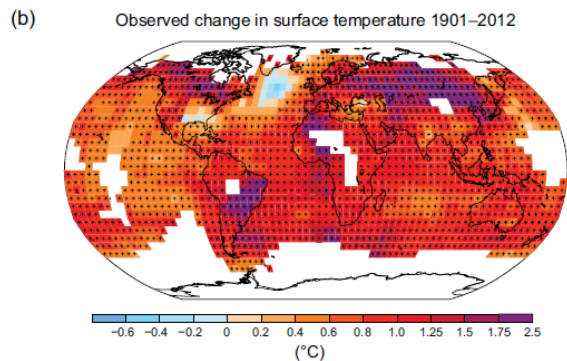

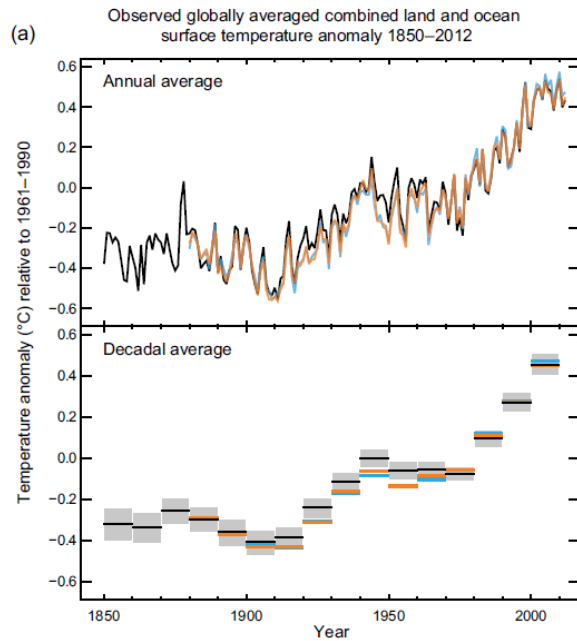

Climate – what's climate?

...climate is the statistics of weather conditions in an area over a long period of time...

(WMO)

- Temperature
- Humidity
- Atmospheric pressure
- Wind
- Atmospheric particle count
- Other meteorological variables

Why are we interested in climate?

Snow cover decreases

Arctic sea ice decreases

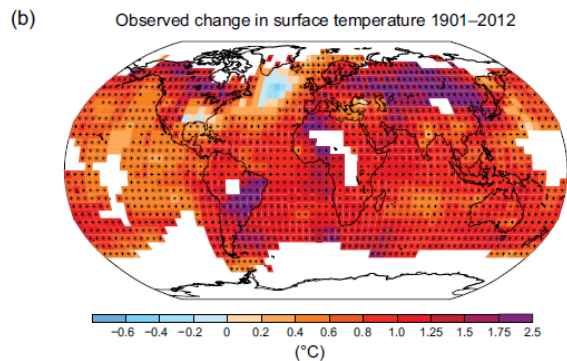

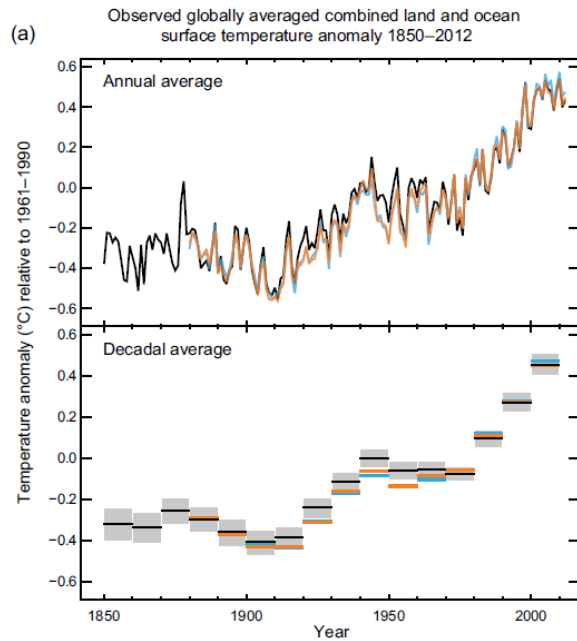

Oceans are warming

Sea level rises

CO₂ – temperature – ocean acidity

Atmos CO₂
increases

Atmos CO₂
increases

Incr acidity
(decr pH)

The Sun warms the Earth

- Black body radiation – Emitted intensity, I , [W/m^2]

$$I = \sigma T^4$$

(σ = Stefan-Boltzmann's constant [$\sigma = 5.67 \cdot 10^{-8} \text{ W}/(\text{m}^2\text{K}^4)$])

- The sun is approximately a black body at 5800 K

- Radiation to the Earth - Solar constant:

(distributed over Earth's shadow area, the area of a circle)

$$F_S = \frac{P}{4\pi d^2} = \frac{4\pi R_S^2 \sigma T_S^4}{4\pi d^2} = 1370 \text{ W}/\text{m}^2$$

- The flux distributed over the entire surface of the Earth (the area of a sphere)

- The radiation flux per area at the Earth's surface becomes:

$$\Phi = \frac{\pi r^2}{4\pi r^2} \cdot F_S = \frac{F_S}{4} \approx \mathbf{340 \text{ W}/\text{m}^2}$$

Figure 7-9 Radiative balance for the Earth

d = Earth's distance from sun
 R_S = Radius of the sun
 $T_S = 5800 \text{ K}$
 P : Power of the Sun

Radiation Balance of the Earth

- Radiation flux at the Earth's surface

$$\Phi = \frac{\pi r^2}{4\pi r^2} \cdot F_s = \frac{F_s}{4} \approx \mathbf{340 \text{ W/m}^2}$$

- Satellites show that the Earth's Albedo is 28% ($A=0.28$)

- **Reflection** by the Earth (average per area)

$$\Phi = F_s A / 4$$

- **Absorption** by the Earth (average per area)

$$\Phi = F_s (1-A) / 4$$

- Radiation balance

- The Earth emits the same amount as is absorbed
- Consider the Earth as a black body:

$$\sigma T_E^4 = F_s (1-A) / 4$$

➔ $T_E = 257 \text{ K}$

- The earth viewed from space

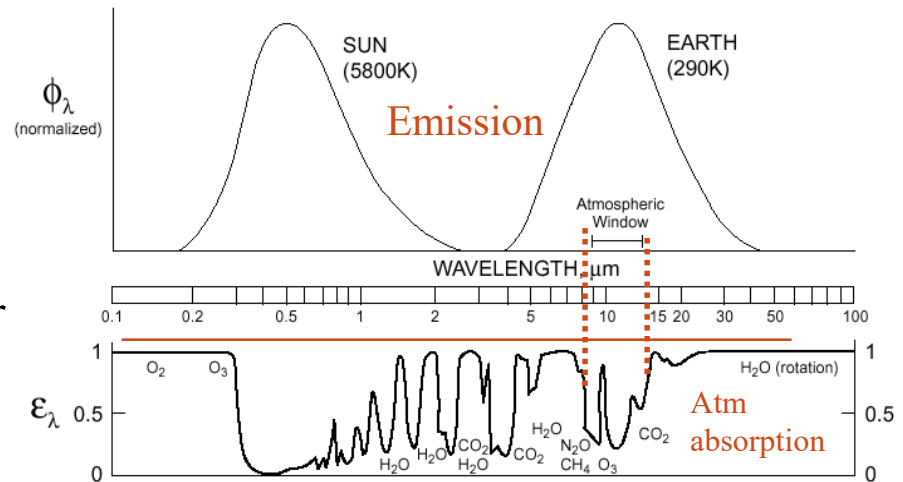

- **Effective temperature** -16°C
- The temperature that the Earth would have had if it did not have an atmosphere (**GHGs**)

The greenhouse effect warms...

- An "insulating" layer of GHGs
- Prevents radiation from penetrating through the atmosphere
- Keeps the energy in the Earth-atmosphere-system
- The Earth's *surface* are heated by the Sun
- The Earth then emits radiation that get trapped by GHGs

Atmospheric Absorption of Radiation

- The sun – solar radiation
 - High temperature – **short wavelength**
- The earth – terrestrial radiation
 - Lower temp. – **longer wavelength**
- UV absorbed by O_2 and O_3
- The atmosphere fairly transparent for solar radiation (H_2O)
- H_2O , CO_2 , CH_4 , N_2O , O_3 and CFC absorbs large fraction of the terrestrial radiation
- Atmospheric window ($\lambda = 8 - 13 \mu m$):
Radiation direct from the surface to space

Radiation Spectrum of the Earth

- The Earth radiation spectrum differs from black body radiation
 - Absorption and re-emission in the atmosphere
 - The atm temp decreases with altitude
 - Temp determines radiation (σT^4) – Less radiation from a cold body
- Combination of black bodies of different temperatures

Black body spectrum
for $T = 320\text{ K}$

Spectrum taken from satellite over North Africa

- Atmospheric “window” (8-13 μm):
 - Weak absorption in the atm \Rightarrow
 - Radiation from **surface** $T \approx 320\text{K}$ (North Africa!)
- CO_2 at 15 μm :
 - $T \approx 215\text{K}$
 - effective emission altitude $\sim 10\text{ km}$
- H_2O (7 & 20 μm):
 - $T \approx 260\text{K}$
 - effective emission altitude $\sim 5\text{ km}$ (precipitation keeps H_2O at low altitudes)
- The greenhouse effect:
 - Atm absorption + atm temp decrease with altitude \Rightarrow
 - Part of the terrestrial emission from lower temp (“deep valleys” in the spectrum) \Rightarrow
 - **Radiation balance**
 - Total emission corresponding to 257 K (T_E) needed
 - \Rightarrow increased overall temperature to compensate for the dips in the spectrum
 - \Rightarrow Increased **surface temperature**

Radiation Balance

Global energy balance (annual mean)

Short wave radiation (in):

- 28% reflected (19% clouds)
- 72% absorbed (47% surface)

Long wave radiation:

- 96% atmosphere → surface

Non-radiative components:

- 24 + 5% heat transport from surface to atmosphere (vapour formation, convection)

The greenhouse effect:

- The balance of the surface
 - $\Phi_{rel} = 22 + 25 + 96 - 24 - 5 = 114\%$
- The greenhouse effect increases the radiation to the surface
 - 14% higher than without an atmosphere

A Simple Climate Model

- **Assumptions on the atmosphere:**
 - Thin, isothermal layer
 - Absorbs fraction **f** of the terrestrial radiation
 - Transparent to solar radiation

Radiation balance:

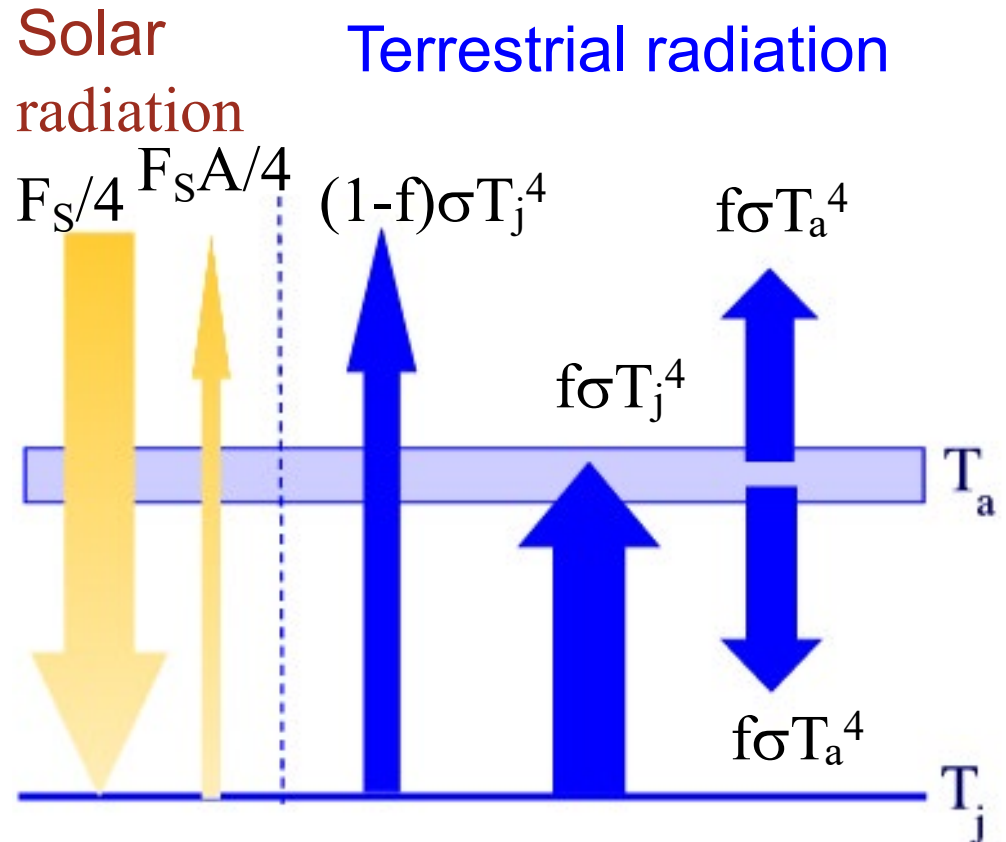

Earth + atmosphere:

$$\frac{F_s(1-A)}{4} = (1-f)\sigma T_j^4 + f\sigma T_a^4$$

The Atmosphere: $f\sigma T_j^4 = 2f\sigma T_a^4$

⇒

$$T_j = \left(\frac{F_s(1-A)}{4\sigma(1-f/2)} \right)^{1/4}$$

Average surface temperature of the Earth: 288 K
- Obtained with $f = 0.77$

Now we have a simple climate model for understanding the atmosphere...

Radiative Forcing

The **initial change** caused by a change in radiative properties(!)
(excluding climate feed-backs)

1. Starting conditions (Equilibrium)

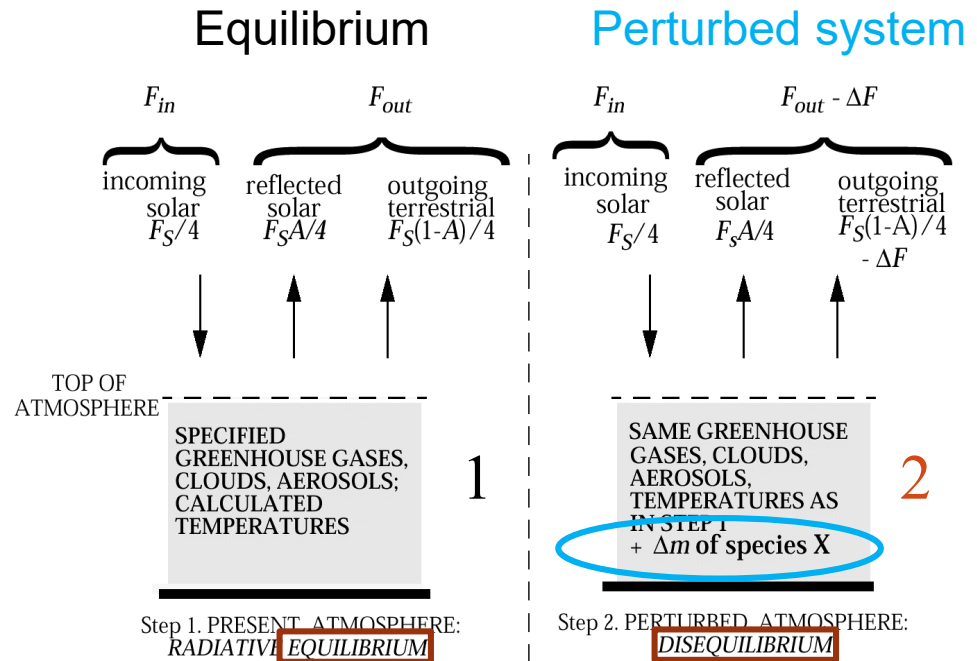

- Radiation model
- Specify system components
- Compute temperature

2. Perturb the system

- Specify new components
- Temperatures are kept unchanged
- Causes difference between incoming and outgoing radiation

- **Radiative Forcing ΔF [W/m^2]**

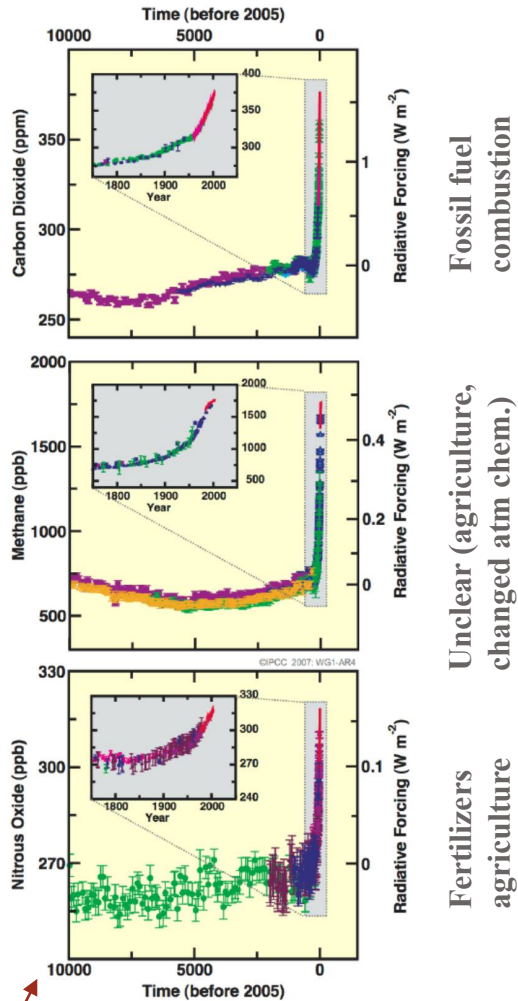

- Positive \rightarrow Warming
- Negative \rightarrow Cooling
- "Theoretical" product (nature does not "freeze" starting temp)
- Frequently used to describe the potential of climate perturbations

$$\Delta F = F_{in,2} - F_{out,2}$$

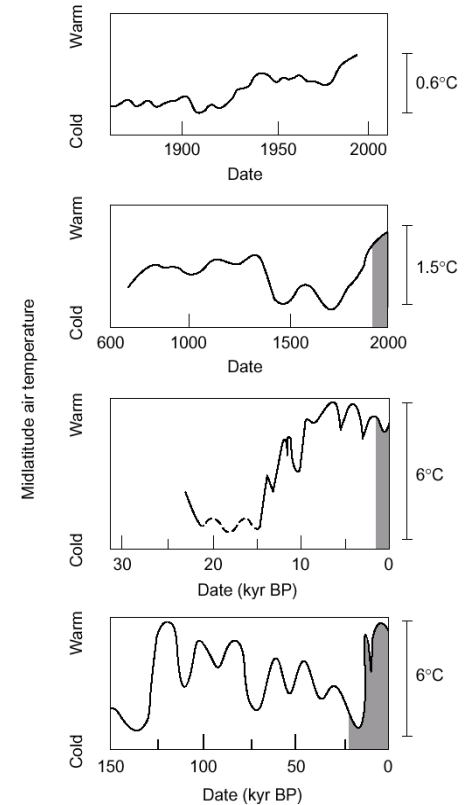

Climate Change Caused by Man

Changes in Greenhouse Gases from ice-Core and Modern Data

Last ice age, 11 500 y ago

- Natural GH effect (CO_2 , H_2O) increases surface temp by 33°C
- Ongoing climate change:
 - Increasing air and ocean temp
 - Reduced snow cover
 - Rising sea level
- Increased GHG concentration has increased the GH effect
- GHG emissions explain climate change?
 - Historical temp variations larger – Due to variation in solar activity
- Natural variations do not explain the increased temperature in the last 200 years
 - Climate models predict further warming – IPCC (UN climate panel):
 - **“It is extremely likely that human influence has been the dominant cause of observed warming since the mid 20th century.”**

Climate Change

- Change of the radiation properties causes:
 - Initial temperature change
 - Feedbacks due to change
- Combines to a climate change

More on clouds next lecture

H₂O feedbacks

- H₂O the most important GHG
 - Human's emissions small compared with the natural sources
- Increase of another GHGs \Rightarrow increased temp \Rightarrow evaporation of H₂O \Rightarrow further increased temp \Rightarrow more evaporation...
- Counteraction
 - cloud formation and precipitation
 - Prevents H₂O from reaching high (cold) altitudes
- The role of clouds in a temperature change is **still** unclear:
 - more H₂O \Rightarrow increased cloudiness \Rightarrow increased albedo
 - more H₂O \Rightarrow larger cloud drops \Rightarrow faster formation of precipitation \Rightarrow reduced cloudiness \Rightarrow reduced albedo
- Large quantitative uncertainties concerning clouds in the climate system

Climate Change

- Feedbacks due to change
 - complicated
 - large quantitative uncertainties
- The initial phase is directly connected with the radiative properties
 - better understood quantitatively
- The potential of climate change of greenhouse gases (radiative forcing) is known with high accuracy

Climate Sensitivity

- How does ΔF relate to a temperature change when feedbacks are neglected?

from (1) and (4) :

Radiative Forcing (greenhouse gases):

$$\begin{aligned}\Delta F &= F_S(1-A)/4 - (1 - \frac{f + \Delta f}{2})\sigma T_0^4 = \\ &= (1 - \frac{f}{2})\sigma T_0^4 - (1 - \frac{f + \Delta f}{2})\sigma T_0^4 = \frac{\Delta f}{2} \sigma T_0^4\end{aligned}\quad (1)$$

Assume a new temperature equilibrium:

$$\frac{F_S(1-A)}{4} = (1 - \frac{f}{2})\sigma T_0^4 = (1 - \frac{f + \Delta f}{2})\sigma(T_0 + \Delta T_0)^4\quad (2)$$

Small perturbations: (neglect second order terms...)

$$(T_0 + \Delta T_0)^4 \approx T_0^4 + 4T_0^3 \Delta T_0\quad (3)$$

Combine (2) and (3)

$$\Delta T_0 = \frac{T_0 \Delta f}{8(1 - \frac{f}{2})}\quad (4)$$

$$\Delta T_0 = \lambda \Delta F;$$

where :

$$\lambda = \frac{1}{4(1 - \frac{f}{2})\sigma T_0^3} = 0.3 \text{ K}/(\text{W}/\text{m}^2)$$

$$(T_0 = 288 \text{ K}; f = 0.77)$$

λ = climate sensitivity parameter

Problem

IPCC estimate that a doubling of the CO₂ concentration causes a radiative forcing (ΔF) of 4.4 W/m². Assuming no feedbacks on temperature change, how much will the average temperature change on earth?

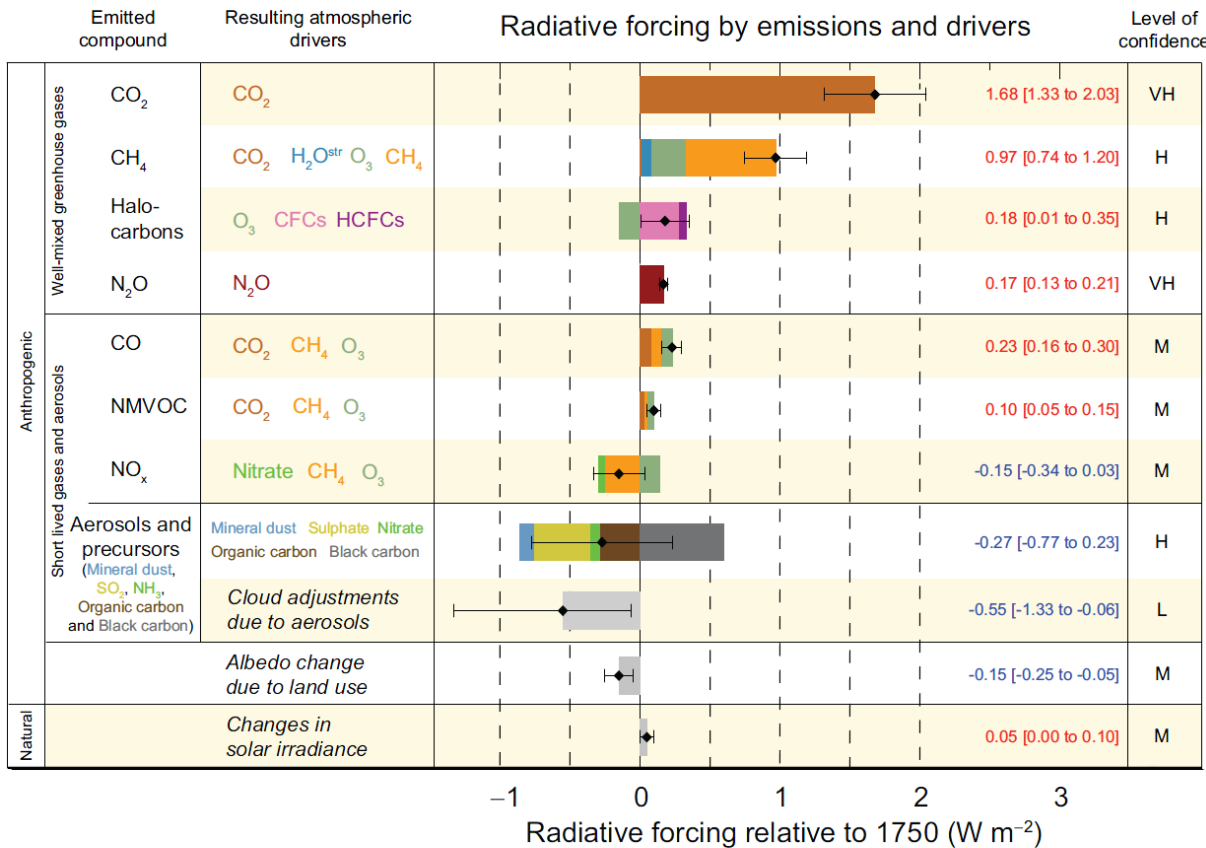

Hint: The climate sensitivity parameter λ

Solution: $\Delta T = \lambda \cdot \Delta F = 0.3 \cdot 4.4 = \mathbf{1.3 \text{ K}}$

...of rapid warming

Feed-back in the climate system gives further warming

Radiative Forcings of Pollutants

- Radiative forcing
 - Expresses change in radiative properties or potential climate change
 - Difficult to translate to temperature change due to feedbacks
- The radiative forcing by greenhouse gases (GHG) quantitatively known
- Larger uncertainties in the direct aerosol effect
- The indirect aerosol effect poorly known quantitatively

Radiative Forcings of Pollutants

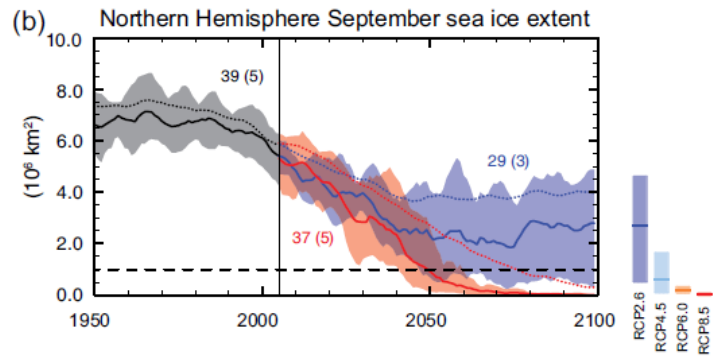

- Anthropogenic ΔF : $+2.3 \text{ W/m}^2$
- Climate sensitivity factor (λ) – neglecting feedbacks:
 - $\Delta T = \lambda \Delta F = 0.3 \times 2.3 = 0.7 \text{ K}$
 - ΔT observed until 2011: 0.8 K
 - Slow feed-backs will result in future warming
- Large uncertainty $1.1 - 3.3 \text{ W/m}^2$
 - Mainly from aerosols
- \Rightarrow Large uncertainties in the climate sensitivity
- \Rightarrow Aerosol forcings have the potential to mask the warming from greenhouse gases
- Might delay detection of dangerous climate change

We have significantly changed the radiative properties

- Difficult to estimate temperature change due to feedbacks

Future scenarios

Future - Temperature and precipitation

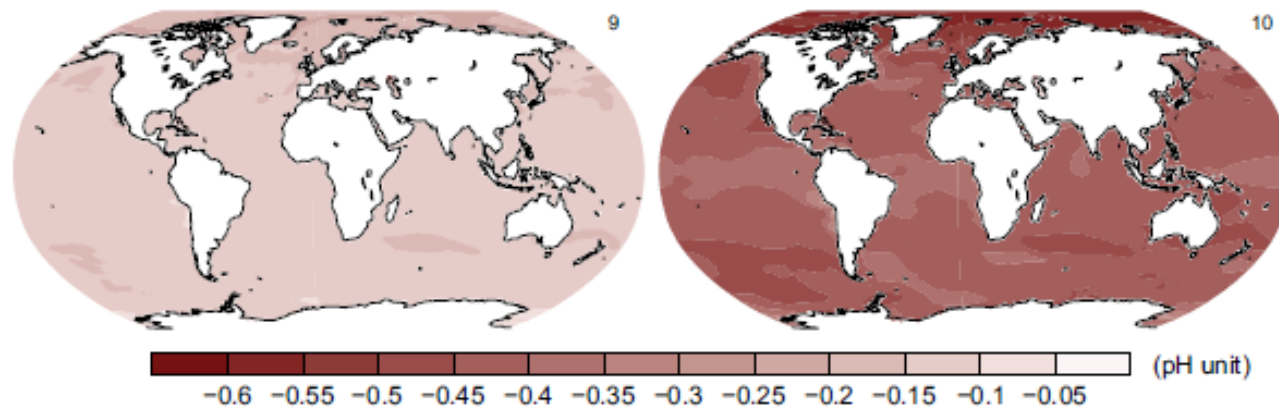

Future – Ice extent and ocean acidity

(c) Northern Hemisphere September sea ice extent (average 2081–2100)

(d) Change in ocean surface pH (1986–2005 to 2081–2100)

What we talked about

The role of the natural atmosphere in the climate system

Human impact on the atmosphere and the climate

- Radiation balance (of the Earth)
- The greenhouse effect
- Radiative forcing
- Climate change (ongoing and future)
